

Problem Solution

The rapid growth of online food delivery services has resulted in the generation of large volumes of customer order data. This data contains valuable information about customer preferences, ordering habits, payment methods, meal choices, ratings, and sales performance. However, when the data is stored in spreadsheets, it becomes difficult to identify meaningful patterns and trends.

The Food Ordering Behavior Analysis Using Tableau project solves this problem by converting raw data into interactive dashboards. The dashboard allows users to analyze customer behavior using various visualizations such as bar charts, pie charts, line charts, maps, and KPI cards. Users can apply filters to compare data based on city, cuisine, meal type, payment method, and ratings.

The solution enables restaurant owners and business managers to identify popular cuisines, understand customer preferences, monitor sales performance, analyze peak ordering hours, and evaluate payment trends. These insights help businesses improve marketing strategies, optimize menu planning, increase customer satisfaction, and support data-driven decision-making.
