

Solution Architecture

The architecture of the Food Ordering Behavior Analysis Using Tableau project follows a systematic process that converts raw data into meaningful business insights.

1. Data Collection:

Food ordering data is collected from the dataset containing customer information, order details, cuisine types, meal categories, payment methods, ratings, order values, and city information.

2. Data Preparation:

The collected data is cleaned using Microsoft Excel by removing duplicate records, correcting missing values, formatting columns, and ensuring data accuracy. The prepared dataset is then imported into Tableau Public.

3. Dashboard Development:

Interactive dashboards are created using Tableau. Various charts, graphs, maps, KPI cards, filters, and parameters are used to present the information in a visually appealing and user-friendly manner.

4. User Interaction:

Users interact with the dashboards by applying filters and selecting different categories such as city, cuisine, meal type, and payment method to analyze customer ordering behavior.

5. Business Insights:

The dashboards generate meaningful insights regarding customer preferences, sales trends, peak ordering times, popular cuisines, payment methods, and customer satisfaction. These insights support better planning, marketing strategies, and business decision-making.

The architecture ensures a smooth flow of information from raw data collection to interactive visualization, providing an efficient and scalable analytical solution.
